源码如下

```php
1  <?php
2   show_source("20.php");
3     echo '<br>';
4  error_reporting(0);
5  function noother_says_correct($temp)
6  {
7      require 'flag.php';
8      $one = ord('1');
9      $nine = ord('9');
10      $number = '3735929054';
11      for ($i = 0; $i < strlen($number); $i++)
12      {
13          $digit = ord($temp{$i});
14          if ( ($digit >= $one) && ($digit <= $nine) )
15          {
16              return "flase";
17          }
18      }
19      if($number == $temp)
20          return $flag;
21  }
22  $temp = $_GET['password'];
23  echo noother_says_correct($temp);
24
25  ?>
```

仔细阅读源码，可以发现需要传入一个和number相等的数，但每一位都不能是1~0之间的
所以这里猜用hex绕过

payload

```
1  ?password=0xdeadc0de
```
